Blockchain Lab 3

Aim: Study on Solidity Programming for creating Smart Contracts

Theory: Solidity is a high-level programming language specifically designed for creating smart contracts on blockchain platforms like Ethereum. Smart contracts are self-executing contracts with the terms and conditions of the agreement directly written into code. Solidity plays a pivotal role in enabling the automation and decentralization of various applications, such as decentralized finance (DeFi), non-fungible tokens (NFTs), and supply chain management, by ensuring the trustworthiness and transparency of these applications through the blockchain. To understand Solidity, one must grasp its core concepts.

One fundamental concept in Solidity is the Ethereum Virtual Machine (EVM), which executes the smart contract code. Smart contracts operate in a trustless environment, meaning they execute autonomously without relying on a central authority. Solidity includes data types, variables, and control structures to facilitate the creation of these self-executing contracts. It also supports inheritance, allowing developers to build on existing smart contracts to create more complex and feature-rich applications.

```
    // Gas spent are not refunded.
    function forever() public {
        // Here we run a loop until all of the gas are spent
        // and the transaction fails
        while (true) {
            i += 1;
        }
    }
}
```

pragma solidity ^0.8.3;

contract z {
    /*
    Which function is called, fallback() or receive()?
```

```
          send Ether
              |
        msg.data is empty?
             / \
           yes  no
           /     \
receive() exists?  fallback()
        /   \
       yes   no
       /      \
   receive()   fallback()
   */

   // Function to receive Ether. msg.data must be empty
   receive() external payable {}

   // Fallback function is called when msg.data is not empty
   fallback() external payable {}

   function getBalance() public view returns (uint) {
       return address(this).balance;
   }
}
```

```
contract SendEther {
    function sendViaTransfer(address payable _to) public payable {
        // This function is no longer recommended for sending Ether.
        _to.transfer(msg.value);
    }

    function sendViaSend(address payable _to) public payable {
        // Send returns a boolean value indicating success or failure.
        // This function is not recommended for sending Ether.
        bool sent = _to.send(msg.value);
        require(sent, "Failed to send Ether");
    }

    function sendViaCall(address payable _to) public payable {
        // Call returns a boolean value indicating success or failure.
        // This is the current recommended method to use.
        (bool sent, bytes memory data) = _to.call{value: msg.value}("");
        require(sent, "Failed to send Ether");
    }
}

contract Charity {
    address public owner;

    constructor() {
```

```
        owner = msg.sender;
    }

    function donate() public payable {}

    function withdraw() public {
        uint amount = address(this).balance;

        (bool sent, bytes memory data) = owner.call{value: amount}("");
        require(sent, "Failed to send Ether");
    }
}
```

Conclusion: Solidity programming has been implemented on Remix IDE.
